

Compiler Examples

- Will use 'gcc' on SUN Sparc to produce some assembly language files for examples
 - ⇒ Do not have a MIPS cross compiler on SUN using GCC
- SPARC is similar to MIPS in that it is a load/store RISC architecture
- Register naming conventions for SPARC
 - ⇒ %o0, %o1, %o2 --- registers for passing values to subroutines. These are called \$a0, \$a1,... in MIPS.
 - ⇒ %i0, %i1, %i2, ... -- registers for receiving arguments in subroutine if new Register window has been allocated (o%i1 = i%i1 in subroutine).
 - ⇒ %fp = framepointer, %sp = stackpointer

Other MIPS vs SPARC differences

- SPARC has register windows (already discussed).
- SPARC has delayed branch
 - ⇒ Instruction after a change of control (branch, jump, subroutine) is always executed
 - ⇒ MIPS has delayed branch also, but it is taken care of in the assembler and the programmer does not see it. The -bare option to XSPIM disables all psuedoinstructions and enables delayed branches, delayed loads.
 - ⇒ Delayed branches are necessary for efficient pipelined implementation (Chapter 6).
- Instructions have SOURCE first, then DEST
 - ⇒ `mov %o0, %io` ; transfer %o0 to %i0

Other MIPS vs SPARC differences

- CALL
 - ⇒ return address placed in OUT7 register (register 15)
 - ⇒ RET instruction does indirect jump using register 15
- JMPL is like CALL except can specify register where return address is placed
 - ⇒ RETL, RET are pseudo instructions that use JMPL to return from a subroutine. Uses register g0.
- No integer multiply instruction

A+B (apusb.c)

```
apusb (a,b)
int a,b;
{
    return(a+b);
}
```

% gcc -S -c apusb.c

No optimization passed to gcc

apusb.s

```
.file "apusb.c"
gcc2_compiled.:
.section ".text"
.align 4
.global apusb
.type apusb,@function
.proc 04
apusb:
!#PROLOGUE# 0
save %sp, -112, %sp
!#PROLOGUE# 1
st %i0, [%fp+68]
st %i1, [%fp+72]
ld [%fp+68], %o0
ld [%fp+72], %o1
add %o0, %o1, %o0
mov %o0, %i0
b .LL2
nop
.LL2:
ret
restore
.LLfel:
.size apusb,.LLfel-apusb
.ident "GCC: (GNU) 2.95.2 19991024 [release]"
```

"save" SPARC instruction is like 'enter' on X86. Allocates a stack frame and register window set.

Save arguments in stack frame. Args passed in %i0, %i1.

get them back into OUT regs (unoptimized, use 'OUT' regis for temp regs).

do the add

return value in %i0

return

destroy stack frame, deallocate window set

apusb.s (optimized)

% gcc -O -s -c apusb.c

```
.file "apusb.c"
gcc2_compiled.:
.section ".text"
.align 4
.global apusb
.type apusb,@function
.proc 04
apusb:
!#PROLOGUE# 0
!#PROLOGUE# 1
retl
add %o0, %o1, %o0
.LLfel:
.size apusb,.LLfel-apusb
.ident "GCC: (GNU) 2.95.2 19991024 [release]"
```

No stack frame, no window register set.

Just the ADD instruction.

Notice 'add' comes after the return instruction because of delayed branch!!!

M*X + B

```

mxb {m,x,b}
int m,x,b;
{
    return (m*x+b);
}

```

% gcc -S -c mxb.c

mx.b.s (optimized)

```

.file      "mxb.c"
gcc2_compiled.:
.global   .umul
.section  ".text"
.align   4
.global   mxb
.type    mxb, #function
.proc    04
mxb:
    !#PROLOGUE# C
    save %sp, -112, %sp
    !#PROLOGUE# 1
    mov %i0, %o0
    call .umul, 0
    mov %i1, %o1
    ret
    restore %o0, %i2, %o1
.LLfel:
    .size   mxb, .LLfel-mxb
    .ident  "GCC: [GNU] 2.95.2 19991024 [release]

```

New window set, sp = sp + -112

No multiply instruction on SPARC. Call a system subroutine for this.

Values (m,x) passed in %i0, %i1.

Return value in %o0

restore window set, also compute final addition of m*x + b. (note that m*x = %o0, %i2 = B.
